DEPARTMENT VISION

To become a global leader in Artificial Intelligence and Data Science by achieving through excellence in teaching, training, and research, to serve the society.

DEPARTMENT MISSION

- To develop students' skills in innovation, problem-solving, and professionalism through the guidance of well-trained faculty.
- To encourage research activities among students and faculty members to address the evolving challenges of industry and society.
- To impart qualities such as moral and ethical values, along with a commitment to lifelong learning.

PROGRAMME EDUCATIONAL OBJECTIVES (PEO's)

PEO 1: Build a successful professional career across industry, government, and academia by leveraging technology to develop innovative solutions for real-world problems.

PEO 2: Maintain a learning mindset to continuously enhance knowledge through experience, formal education, and informal learning opportunities.

PEO 3: Demonstrate an ethical attitude while excelling in communication, management, teamwork, and leadership skills.

PEO 4: Utilize engineering, problem-solving, and critical thinking skills to drive social, economic, and sustainable impact.

PROGRAMME OUTCOME (PO's)

PO1: Engineering Knowledge: Apply the knowledge of mathematics, science, engineering fundamentals and an engineering specialization to the solution of complex engineering problems.

PO2: Problem Analysis: Identify, formulate, review research literature, and analyze complex engineering problems reaching substantiated conclusions using first principles of mathematics, natural sciences, and engineering sciences.

PO3: Design / Development of solutions: Design solutions for complex engineering problems and design system components or processes that meet the specified needs with appropriate consideration for the public health and safety, and the cultural, societal, and environmental considerations.

PO4: Conduct investigations of complex problems: Use research-based knowledge and research methods including design of experiments, analysis and interpretation of data, and synthesis of the information to provide valid conclusions.

PO5: Modern tool usage: Create, select, and apply appropriate techniques, resources, and modern engineering and IT tools including prediction and modeling to complex engineering activities with an understanding of the limitations.

PO6: The engineer and society: Apply reasoning informed by the contextual knowledge to assess societal, health, safety, legal and cultural issues and the consequent responsibilities relevant to the professional engineering practice.

PO7: Environment and sustainability: Understand the impact of the professional engineering solutions in societal and environmental contexts, and demonstrate the knowledge of, and need for sustainable development.

PO8: Ethics: Apply ethical principles and commit to professional ethics and responsibilities and norms of the engineering practice.

PO9: Individual and team work: Function effectively as an individual and as a member or leader in diverse teams, and in multidisciplinary settings.

PO10: Communication: Communicate effectively on complex engineering activities with

the engineering community and with society at large, such as, being able to comprehend and write effective reports and design documentation, make effective presentations, and give and receive clear instructions.

PO11: Project management and finance: Demonstrate knowledge and understanding of the engineering management principles and apply these to one's own work, as a member and leader in a team, to manage projects and in multidisciplinary environments.

PO12: Life-long learning: Recognize the need for and have the preparation and ability to engage in independent and lifelong learning in the broadest context of technological change.

PROGRAM SPECIFIC OUTCOMES (PSO's)

A graduate of the Artificial Intelligence and Data Science Learning Program will demonstrate:

PSO 1: Foundation Skills: Apply the principles of artificial intelligence and data science by leveraging problem-solving skills, inference, perception, knowledge representation, and learning techniques.

PSO 2: Problem-Solving Skills: Apply engineering principles and AI models to solve real-world problems across domains, delivering cutting-edge solutions through innovative ideas and methodologies.

PSO 3: Successful Progression: Utilize interdisciplinary knowledge to identify problems and develop solutions, a passion for advanced studies, innovative career pathways to evolve as an ethically responsible artificial intelligence and data science professional, with a commitment to society.

COURSE OBJECTIVE

To understand the fundamental principles of data privacy and security, including key concepts like the CIA Triad

(Confidentiality, Integrity, Availability).

 To gain knowledge of cryptographic techniques, encryption algorithms, and their applications in safeguarding

sensitive data.

 To identify and analyze data threats, privacy attacks, and the strategies to mitigate risks.

 To study emerging trends and innovative approaches in data security and privacy, such as ID4D initiatives,

continuous authentication, and cancellable authentication methods

 To understand the fundamental principles of data privacy and security, including key concepts like the CIA Triad

(Confidentiality, Integrity, Availability).

COURSE OUTCOME

At the end of the course the student will be able to :

 Understand the of data privacy and security, including the CIA triad

 Design and implement cryptographic solutions to ensure data security

 Analyze the access control and authentication mechanisms to enhance system security

 Analyze the threats, vulnerabilities, and risks in data systems

 Apply the contemporary standards for data protection in real-world scenarios

SDG GOALS

GOAL 1: No Poverty – End poverty in all its forms everywhere

GOAL 2: Zero Hunger – End hunger, achieve food security and improved nutrition and promote sustainable agriculture

GOAL 3: Good Health and Well-being – Ensure healthy lives and promote well-being for all at all ages

GOAL 4: Quality Education – Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all

GOAL 5: Gender Equality – Achieve gender equality and empower all women and girls

GOAL 6: Clean Water and Sanitation – Ensure availability and sustainable management of water and sanitation for all

GOAL 7: Affordable and Clean Energy – Ensure access to affordable, reliable, sustainable and modern energy for all

GOAL 8: Decent Work and Economic Growth – Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all

GOAL 9: Industry, Innovation and Infrastructure – Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation

GOAL 10: Reduced Inequality – Reduce inequality within and among countries

GOAL 11: Sustainable Cities and Communities – Make cities and human settlements inclusive, safe, resilient and sustainable

GOAL 12: Responsible Consumption and Production – Ensure sustainable consumption and production patterns

GOAL 13: Climate Action – Take urgent action to combat climate change and its impacts

GOAL 14: Life Below Water – Conserve and sustainably use the oceans, seas and marine resources for sustainable development

GOAL 15: Life on Land – Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation

GOAL 16: Peace and Justice Strong Institutions – Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels

GOAL 17: Partnerships to achieve the Goal – Strengthen the means of implementation and revitalize the global partnership for sustainable development.

SUSTAINABLE DEVELOPMENT GOALS

SDG 9 | Industry, Innovation and Infrastructure

Justification:
The Cyber-Resilient Smart Manufacturing system enhances modern industrial infrastructure by integrating **Artificial Intelligence, Industrial IoT, and cybersecurity automation**. The platform introduces innovative solutions such as **AI-based anomaly detection, digital twin technology, and automated recovery mechanisms** to ensure continuous production even during cyberattacks. This promotes the development of **resilient, scalable, and intelligent manufacturing systems**, supporting sustainable industrial growth and technological advancement in Industry 4.0 environments.

SDG 12 | Responsible Consumption and Production

Justification:
The system improves production efficiency by minimizing downtime and preventing unnecessary resource wastage during disruptions. By ensuring **continuous and optimized manufacturing operations**, it reduces material loss, energy waste, and operational inefficiencies caused by system failures or cyber incidents. This contributes to more **sustainable production practices and efficient resource utilization** in smart factories.

SDG 16 | Peace, Justice and Strong Institutions

Justification:
The project strengthens industrial cybersecurity by ensuring **secure, reliable, and transparent operations** in manufacturing environments. Through features like **real-time monitoring, automated threat isolation, and secure system recovery**, it protects critical infrastructure from cyber threats. This enhances **trust, accountability, and operational integrity** in industries, supporting strong and secure institutional frameworks.

SDG 8 | Decent Work and Economic Growth

Justification:
By preventing production shutdowns and reducing financial losses due to cyberattacks, the system supports **stable industrial operations and economic growth**. It ensures workforce stability by avoiding sudden disruptions in manufacturing processes and contributes to a **safe and secure working environment** in smart industries.

ABSTRACT

Smart manufacturing environments rely heavily on interconnected Information Technology (IT) and Operational Technology (OT) systems, making them highly efficient but also increasingly vulnerable to cyber threats. Traditional cybersecurity approaches in industrial settings are often limited to isolated tools and reactive incident response mechanisms that activate only after significant disruption has occurred. This creates serious risks, as a single cyberattack can halt production, damage equipment, and disrupt supply chains, leading to financial losses and reduced operational reliability. Moreover, the lack of integration between IT security systems and OT control environments further increases the difficulty of detecting and responding to threats in a timely manner.

To address these challenges, this project proposes a cyber-resilient smart manufacturing framework designed to ensure continuous production even during active cyber incidents. The system incorporates AI-driven anomaly detection to continuously monitor industrial environments and identify abnormal behavior in real time by analyzing machine telemetry, network traffic, and user activity patterns. Once a threat is detected, automated mechanisms isolate compromised zones, restrict unauthorized access, and prevent the spread of attacks across interconnected systems.

In addition, the framework integrates a synchronized digital twin environment that acts as a real-time backup of physical operations. This allows critical processes to continue through simulated or alternate workflows even if physical systems are disrupted. The system also includes intelligent workload redistribution, ensuring that unaffected machines and production lines continue functioning without interruption.

Furthermore, self-healing recovery techniques enable rapid restoration of affected components, including machines, PLC configurations, and software systems, using trusted backups and automated workflows. This significantly reduces dependency on manual intervention and speeds up recovery time. The system also includes a real-time dashboard that provides comprehensive visibility into system health, threat levels, production status, and recovery progress through dynamic analytics, visual indicators, and alert mechanisms.

By integrating intelligent automation with resilience engineering, the proposed framework not only improves cybersecurity but also enhances operational efficiency, adaptability, and decision-making capabilities. It enables industries to shift from reactive security models to proactive and resilient systems, ensuring reliable, secure, and uninterrupted production in modern Industry 4.0 environments.

CASE STUDY: Jaguar Land Rover (JLR) Production Halt (2020–2023)

The production disruptions experienced by Jaguar Land Rover between 2020 and 2023 provide a clear illustration of the vulnerabilities present in modern smart manufacturing systems. As a globally recognized automobile manufacturer, Jaguar Land Rover operates highly integrated production environments that rely on advanced automation, robotic assembly lines, and tightly coordinated global supply chains. During this period, the company faced multiple production halts, primarily due to semiconductor shortages and widespread supply chain disruptions. These issues were further intensified by pandemic-related constraints, geopolitical tensions, and the increasing complexity of global logistics networks.

The disruptions had a significant operational and financial impact on the organization. Several assembly lines were temporarily shut down, leading to reduced production output and delays in delivering vehicles to customers. The company also experienced increased operational costs due to rescheduling, resource underutilization, and inefficiencies in workforce management. The root causes of these disruptions can be traced to a heavy dependence on just-in-time manufacturing strategies, which minimize inventory but increase vulnerability to supply shortages, as well as reliance on interconnected digital systems that coordinate production and supply chain activities.

This case study is particularly relevant to cyber-resilient smart manufacturing as it demonstrates how modern industrial systems are highly sensitive to disruptions, whether physical or digital. While the JLR disruptions were primarily due to supply chain issues, a similar or even greater impact could result from a cyberattack targeting critical industrial components such as PLCs, ERP systems, or Industrial IoT networks. For example, a ransomware attack on production control systems or unauthorized access to supply chain management platforms could lead to sudden production shutdowns, data corruption, and loss of operational control.

The proposed Cyber-Resilient Smart Manufacturing framework directly addresses these challenges by introducing mechanisms that enhance system robustness and adaptability. Through real-time monitoring, the system continuously analyzes operational data to detect anomalies and potential threats at an early stage. Automated threat detection and isolation prevent the spread of disruptions across the manufacturing environment, while digital twin-based continuity mechanisms enable production processes to continue in a controlled backup environment. In addition, self-healing recovery systems ensure rapid restoration of affected components with minimal human intervention.

Overall, the Jaguar Land Rover case highlights the critical need for resilience in modern manufacturing systems. It emphasizes that industries must move beyond traditional risk management and adopt intelligent, adaptive frameworks capable of maintaining operational continuity under both physical and cyber disruptions. The integration of cybersecurity, automation, and resilience engineering, as proposed in this project, plays a vital role in ensuring uninterrupted production and long-term sustainability in Industry 4.0 environments.

ACKNOWLEDGEMENT

Initially we thank the Almighty for being with us through every walk of our life and showering his blessings through the endeavor to put forth this report. Our sincere thanks to our Chairman **Mr. S.MEGANATHAN, B.E, F.I.E.**, our Vice Chairman **Mr. ABHAY SHANKAR MEGANATHAN, B.E., M.S.,** and our respected Chairperson **Dr. (Mrs.) THANGAM MEGANATHAN**, **Ph.D.,** for providing us with the requisite infrastructure and sincere endeavoring in educating us in their premier institution.

Our sincere thanks to **Dr. S.N. MURUGESAN, M.E., Ph.D.,** our beloved Principal for his kind support and facilities provided to complete our work in time. We express our sincere thanks to **Dr. J.M. GNANASEKAR, M.E., Ph.D.,** Professor and Head of the Department of Artificial Intelligence and Data Science for his guidance and encouragement throughout the project work. We convey our sincere and deepest gratitude to our internal guide, **Dr. S. SURESH KUMAR, M.E., Ph.D.,** Professor, Department of Artificial Intelligence and Data Science. Rajalakshmi Engineering College for his valuable guidance throughout the course of the project.

CHAPTER 1

INTRODUCTION

1.1 GENERAL

With the rapid evolution of Industry 4.0 technologies, modern factories are increasingly adopting interconnected systems that combine robotics, Industrial Internet of Things (IIoT), cloud computing, artificial intelligence, and real-time automation. These smart manufacturing environments improve productivity, efficiency, and decision-making by integrating Information Technology (IT) systems with Operational Technology (OT) systems. IT systems manage enterprise functions such as planning, analytics, and communication, while OT systems control physical production equipment such as programmable logic controllers (PLCs), sensors, robotic arms, and conveyor systems. Although this integration offers major operational benefits, it also creates serious cybersecurity challenges.

Traditional manufacturing systems were largely isolated from enterprise networks and external communication channels. However, in modern smart factories, production machines are connected to internal networks, cloud platforms, remote monitoring systems, and third-party vendors. As a result, cyber threats such as ransomware, malware, insider attacks, phishing, and unauthorized remote access can spread rapidly across connected environments. A single successful cyberattack can stop production lines, corrupt control systems, damage machinery, compromise sensitive industrial data, and disrupt supply chains.

Many current industrial cybersecurity solutions focus mainly on attack prevention using firewalls, antivirus tools, and access controls. While these tools are important, they are not sufficient because no organization can guarantee complete prevention of cyberattacks. Once attackers bypass defenses, factories often face shutdowns, manual recovery processes, and major financial losses. Therefore, industries now require systems that not only prevent attacks but also continue operating during incidents and recover rapidly afterward.

To address this challenge, this project proposes **Cyber-Resilient Smart Manufacturing**, an intelligent framework designed to maintain production continuity even when cyberattacks occur. The system combines AI-driven anomaly detection, automated threat isolation, digital twin backup environments, self-healing recovery mechanisms, and real-time monitoring dashboards. Instead of waiting until an attack causes total failure, the framework detects suspicious behavior early, isolates affected systems, and shifts operations to safe backup environments with minimal disruption.

The following sections describe the fundamental technologies and components that form the basis of the proposed Cyber-Resilient Smart Manufacturing framework, including threat detection, IT-OT segmentation, digital twin continuity systems, AI-assisted recovery, and visualization of operational resilience.

1.1.1 IT–OT Integrated Smart Manufacturing Environment

Modern smart factories operate through the close integration of IT and OT networks. IT systems manage enterprise-level functions such as production planning, inventory systems, ERP platforms, employee communication, and cloud analytics. OT systems directly control physical manufacturing operations including sensors, actuators, robotic systems, machine controllers, and automated assembly lines.

This integration enables real-time coordination between business decisions and factory execution. For example, inventory shortages can automatically adjust production schedules, and predictive maintenance alerts can prevent machine failure. However, if IT networks are compromised, attackers may gain indirect access to critical OT environments. Therefore, strong segmentation, secure communication, and continuous monitoring are necessary to protect interconnected manufacturing ecosystems.

1.1.2 AI-Based Threat Detection and Monitoring

Cyberattacks in industrial environments often begin with abnormal behavior such as unusual login attempts, unexpected machine commands, unauthorized network traffic, or suspicious data transfers. Manual monitoring is insufficient because factories generate large volumes of operational data every second.

The proposed system uses Artificial Intelligence and Machine Learning techniques to continuously analyze network logs, sensor behavior, command patterns, and system performance. Algorithms detect deviations from normal operating behavior and generate early alerts. Examples include unexpected robot movement sequences, abnormal PLC instructions, or unusual traffic between IT and OT devices.

By identifying threats in their early stages, the system reduces attack impact and enables faster automated response.

1.1.1 Automated Threat Isolation

When a cyber threat is detected, rapid containment is essential. In many factories, attackers move laterally from one machine or network zone to another. This can quickly escalate a minor compromise into a plant-wide shutdown.

The proposed framework includes an automated isolation engine that immediately disconnects compromised devices, network segments, or control zones from the rest of the factory. This prevents malware propagation while allowing unaffected production areas to continue operating.

For example, if one robotic cell shows suspicious behavior, only that zone is isolated while adjacent production lines remain functional. This containment-first approach significantly improves resilience and minimizes operational downtime.

1.1.2 Digital Twin Backup for Operational Continuity

A digital twin is a virtual replica of a physical manufacturing system that mirrors real-time machine states, workflows, and production parameters. In the proposed framework, the digital twin operates in parallel with the physical factory.

If cyberattacks disrupt physical control systems, selected operations can switch temporarily to the synchronized digital twin environment or backup control layer. This enables continued planning, simulation, and controlled fallback operations while recovery occurs.

The digital twin also helps test incident-response strategies safely without affecting real equipment. By combining cybersecurity with operational simulation, the system ensures continuity even during severe disruptions.

1.1.5 Self-Healing Recovery Mechanism

After threats are contained, rapid recovery is critical. Traditional recovery often depends on manual troubleshooting, software reinstallation, and controller reconfiguration, which may take hours or days.

The proposed system includes self-healing mechanisms that automatically restore affected systems using clean backups, validated configurations, and predefined recovery workflows. Once a threat is neutralized, compromised machines, controllers, or servers are reset to safe operational states.

This reduces dependency on human intervention, speeds restoration, and ensures that production resumes with minimal delay.

1.1.6 Visualization of Security and Production Status

Complex cyber incidents require clear operational visibility. Therefore, the framework includes a dashboard that displays real-time factory health, attack alerts, isolated zones, machine availability, recovery progress, and production continuity status.

Administrators can monitor threat levels, affected systems, and operational performance through charts, heatmaps, alerts, and timeline views. This transforms technical cybersecurity data into actionable decision support for plant managers and security teams.

Visualization improves coordination, accelerates incident response, and supports informed management decisions during critical events.

1.2 OBJECTIVES

The primary objective of this project is to develop a cyber-resilient smart manufacturing framework that ensures production continuity during cyberattacks. The system uses AI-based anomaly detection to identify threats in real time and automated isolation techniques

to contain compromised systems. It incorporates digital twin technology to maintain operations during disruptions and self-healing mechanisms for rapid recovery. Additionally, dashboard visualization provides clear operational awareness and security monitoring. Overall, the system aims to reduce downtime, strengthen industrial cybersecurity, and create resilient smart factory environments.

1.3 EXISTING SYSTEM

In the current industrial ecosystem, most manufacturing cybersecurity systems primarily focus on preventive mechanisms such as firewalls, antivirus software, VPN access, password policies, and basic network monitoring tools. While these approaches are essential for reducing risks, they are often insufficient against advanced and sophisticated cyberattacks that can bypass traditional defenses. Once a breach occurs, many factories still depend on manual incident response processes, where affected machines are shut down, networks are disconnected, and engineers manually diagnose and resolve the issue. This reactive approach leads to significant production delays, increased downtime, revenue loss, and disruptions across the supply chain.

Another major limitation of existing systems is the lack of proper segmentation between Information Technology (IT) and Operational Technology (OT) networks. Without strong isolation mechanisms, cyberattacks originating in enterprise systems can easily propagate into critical production environments, causing widespread operational failures. Furthermore, most traditional manufacturing setups do not implement synchronized digital twin backups or automated recovery workflows, making it difficult to maintain continuity during disruptions. In addition, existing solutions offer limited real-time visibility into both cybersecurity status and production performance. Security teams and production managers often operate in silos, resulting in slower coordination and delayed response during critical incidents. These limitations highlight the need for advanced, integrated, and resilience-focused cybersecurity frameworks in modern smart manufacturing systems.

1.4 PROPOSED SYSTEM

The proposed system introduces Cyber-Resilient Smart Manufacturing, an intelligent platform designed to protect factory operations before, during, and after cyberattacks. The framework continuously monitors industrial systems using AI-driven analytics to detect suspicious behavior at an early stage. Once a threat is identified, automated containment mechanisms isolate affected devices or zones while allowing unaffected production to continue. The system incorporates a synchronized digital twin environment that acts as a backup layer, enabling critical workflows to continue even if physical systems are disrupted. After containment, self-healing modules automatically restore affected machines, PLC configurations, and network settings using trusted backups. A real-time dashboard provides administrators with alerts, system status, and recovery progress. Overall, the system enhances industrial resilience by moving beyond prevention to ensure continuous and secure operations. Additionally, it offers strong traceability by logging all incidents and recovery actions with timestamps, supporting effective analysis and compliance.

CHAPTER 2

LITERATURE SURVEY

2.1 OVERVIEW

The evolution of Industry 4.0 has significantly transformed traditional manufacturing into highly intelligent and interconnected smart manufacturing systems. These systems integrate advanced technologies such as Industrial Internet of Things (IIoT), cloud computing, artificial intelligence, and cyber-physical systems to enable real-time data exchange, automation, and data-driven decision-making across production environments. This integration allows factories to optimize performance, improve efficiency, reduce downtime, and support predictive maintenance. However, the same interconnectedness that enhances productivity also introduces serious cybersecurity challenges. As industrial systems become connected to enterprise networks, cloud platforms, and external vendors, they are increasingly exposed to a wide range of cyber threats that can directly impact physical production processes.

Research indicates that smart manufacturing environments rely heavily on interconnected devices, sensors, programmable logic controllers (PLCs), and communication networks, which expand the attack surface for cyber threats. These systems are vulnerable to attacks such as malware injection, ransomware, unauthorized remote access, data manipulation, and insider threats. Unlike traditional IT systems, attacks on industrial environments can have physical consequences, including equipment damage, production halts, and safety risks. Furthermore, many legacy Industrial Control Systems were originally designed for isolated operation and lack built-in security features, making them highly susceptible to modern cyberattacks.

Due to the dynamic, distributed, and real-time nature of these systems, traditional security mechanisms such as firewalls, antivirus software, and access control policies are no longer sufficient. As a result, recent research has shifted towards the concept of cyber resilience, which focuses not only on preventing attacks but also on ensuring that systems can continue operating during disruptions, recover quickly, and adapt to evolving threats. Cyber-resilient frameworks incorporate AI-based anomaly detection, automated threat response, digital twin technology, and self-healing recovery mechanisms to maintain operational continuity. This shift from prevention-only strategies to resilience-based approaches is essential for ensuring the reliability, safety, and sustainability of modern smart manufacturing systems.

2.2 LITERATURE SURVEY

Research in the field of smart manufacturing cybersecurity, cyber resilience, AI-based monitoring, and digital twin systems has gained significant attention due to the rapid increase in industrial cyberattacks. With the adoption of Industry 4.0 technologies, manufacturing environments have become highly interconnected, making them more efficient but also more vulnerable to cyber threats. Several studies have focused on

improving security, operational continuity, and automated recovery in such environments. The work of S. Lee, B. Bagheri, and H. Kao (2015) introduced a cyber-physical systems architecture that integrates machines, sensors, and enterprise systems through digital communication, laying the foundation for smart factories. However, their study also highlighted that increased connectivity leads to higher cybersecurity risks. Reports from IBM Security (2024) further emphasize that the manufacturing sector is one of the most targeted by cyberattacks, with significant financial losses due to ransomware, operational downtime, and supply chain disruptions. Similarly, E. Byres and J. Lowe (2004) analyzed Industrial Control Systems and demonstrated that these systems, originally designed for isolated environments, are not capable of handling modern cyber threats effectively.

In addition, Gartner (2023) identified digital twin technology as a key enabler for operational simulation, predictive maintenance, and resilience planning, as it allows real-time mirroring of physical systems and supports continuity during disruptions. The study by A. Humayed et al. (2017) provided a comprehensive analysis of threats across industrial components such as sensors, PLCs, and communication protocols, highlighting the need for combined cyber and physical security approaches. Frameworks like MITRE ATT&CK for ICS (2024) offer structured insights into attacker tactics such as lateral movement and unauthorized command execution, while the National Institute of Standards and Technology (NIST) cybersecurity framework provides guidelines for identifying, protecting, detecting, responding to, and recovering from cyber incidents in industrial environments.

Further contributions by P. Derler, E. Lee, and A. Sangiovanni-Vincentelli (2012) emphasize the importance of modeling interconnected systems where software directly influences physical processes, supporting the concept of digital twins. McKinsey & Company (2024) highlights that resilience, along with automation, is a key factor for future manufacturing competitiveness. Additionally, Y. Zhang et al. (2021) demonstrated the effectiveness of AI-based anomaly detection models in identifying abnormal machine behavior and network activities in real time.

Overall, these studies collectively indicate that modern manufacturing cybersecurity must move beyond traditional prevention-based approaches. The integration of AI-driven monitoring, digital twin-based continuity systems, automated recovery mechanisms, and real-time analytics forms the foundation of cyber-resilient smart manufacturing systems capable of maintaining production continuity even during cyberattacks. However, despite these advancements, many existing solutions still lack a unified framework that integrates real-time threat detection, automated containment, digital twin-based continuity, and self-healing recovery into a single system.

In addition, challenges such as scalability across large industrial networks, high implementation costs, lack of skilled cybersecurity personnel, and difficulty in integrating legacy systems further limit the effectiveness of current approaches. Many organizations also struggle with real-time coordination between IT and OT teams, which delays incident response and recovery actions. Therefore, there is a growing need for intelligent, automated, and scalable solutions that can adapt to dynamic industrial environments. This gap highlights the importance of developing an end-to-end cyber-resilient architecture, which is effectively addressed by the proposed system in this project.

CHAPTER 3

SYSTEM DESIGN

3.1 PRODUCTION INPUT AND DATA HANDLING

Unlike traditional standalone industrial systems, the proposed Cyber-Resilient Smart Manufacturing framework operates on a continuous data-driven workflow rather than isolated machine operations. In this approach, production equipment, sensors, controllers, enterprise systems, and network devices continuously generate operational data in real time. These inputs are systematically collected, processed, and analyzed to detect potential threats, maintain operational continuity, and automate recovery actions. When factory devices are integrated into the framework, the system gathers telemetry data such as machine status, PLC commands, sensor readings, network logs, user access records, and production metrics. This collected information forms a baseline of normal operational behavior, which is used to identify anomalies during runtime. Whenever suspicious activity is detected, the system automatically triggers containment and continuity mechanisms to prevent further disruption.

The data handling process involves real-time collection of sensor and machine data, continuous monitoring of network traffic and access logs, storage of relevant operational metadata, and processing through AI-based anomaly detection models. The system also retrieves baseline operating patterns for comparison and initiates automated response actions when incidents are detected. To ensure security and efficiency, only essential operational information such as machine identifiers, production states, timestamps, network activity, and recovery logs are stored, while sensitive credentials and confidential design data are excluded from general monitoring storage. This continuous and intelligent data-driven approach enhances the security of manufacturing operations by reducing dependence on static security rules and manual supervision.

3.2 DEVELOPMENT ENVIRONMENT

The Cyber-Resilient Smart Manufacturing system is implemented using a combination of industrial monitoring tools, artificial intelligence frameworks, simulation environments, and web technologies that support real-time resilience management. The backend of the system is developed using Python with frameworks such as Flask or FastAPI, which handle device communication, alert processing, recovery workflows, and dashboard APIs. These lightweight server environments enable efficient interaction between industrial interfaces and analytics engines.

The system utilizes several software libraries for processing manufacturing data, including Pandas and NumPy for operational data handling, as well as Scikit-learn and TensorFlow for anomaly detection models. Additionally, OpenCV is used for camera-based equipment monitoring, while communication between industrial devices is supported through protocols such as MQTT and OPC UA. Visualization of system data is achieved using tools like Matplotlib and Plotly. The digital twin environment is developed using

simulation tools such as MATLAB Simulink, AnyLogic, and Siemens digital twin platforms, or through custom Python-based simulation models. Development and debugging activities are carried out using Visual Studio Code, which provides strong support for scripting, version control, and integration.

3.2.1 HARDWARE SPECIFICATIONS

The Cyber-Resilient Smart Manufacturing framework can be effectively developed and tested on a standard workstation or an industrial-grade server equipped with sufficient computational resources to handle real-time industrial workloads. A recommended hardware configuration includes a high-performance multi-core processor such as an Intel Core i7 or AMD Ryzen 7 (or higher), which ensures efficient execution of data processing, AI model computations, and system-level operations. The system should be supported by a minimum of 16 GB RAM to handle large volumes of real-time data streams, concurrent processes, and memory-intensive analytics tasks. Additionally, storage of at least 512 GB SSD is required to enable fast data access, logging, and retrieval, which is critical for continuous monitoring and recovery operations.

The processor should operate at a speed of 2.5 GHz or higher to maintain low latency in data processing and real-time response mechanisms. Stable network connectivity through LAN or high-speed Wi-Fi is essential to ensure uninterrupted communication between industrial devices, servers, and monitoring dashboards. Furthermore, optional GPU support can be integrated to significantly enhance the performance of advanced AI and machine learning models, particularly for tasks such as anomaly detection, predictive analytics, and digital twin simulations. In large-scale industrial environments, scalable server configurations or cloud-based infrastructure can also be considered to support higher data loads and distributed processing. Overall, these hardware specifications provide the necessary foundation for efficient real-time analytics, accurate simulation of digital twins, rapid threat detection, and seamless dashboard visualization, thereby ensuring reliable and resilient system performance.

3.2.2 SOFTWARE SPECIFICATIONS

The software stack used in the system integrates both frontend and backend technologies to provide seamless monitoring and control. The frontend interface is developed using React.js along with standard web technologies such as HTML, CSS, and JavaScript, enabling administrators to monitor machine status, receive real-time alerts, analyze threats, and track recovery actions through an interactive interface. The backend is implemented using Python with frameworks like Flask or FastAPI to manage data processing, communication, and system logic. Industrial communication is facilitated using protocols such as OPC UA, MQTT, and Modbus integration tools to ensure reliable data exchange between devices. AI-based threat detection and analysis are performed using libraries such as Scikit-learn, TensorFlow, and PyTorch. Data storage and logging are managed using databases like MySQL, PostgreSQL, and optionally MongoDB. Simulation and digital twin technologies, including MATLAB Simulink, AnyLogic, and Siemens platforms, are used to model, test, and optimize system performance in a virtual environment before deployment.

3.3 ARCHITECTURE

The Cyber-Resilient Smart Manufacturing platform follows a layered architecture that integrates industrial. The system architecture is designed as a multi-layered framework consisting of five main components: the User Interface Layer, Data Acquisition Layer, Threat Detection Layer, Resilience and Recovery Layer, and Analytics and Reporting Layer. This structured approach ensures modularity, scalability, and efficient coordination among different system functions in a smart manufacturing environment.

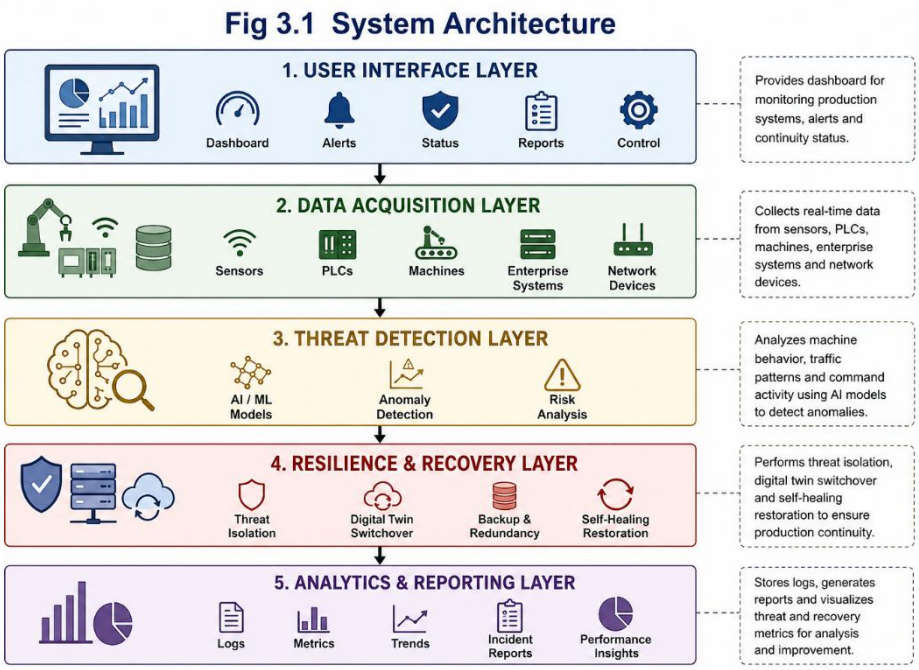

Fig 3.1 System Architecture

The User Interface Layer acts as the interaction point for administrators, providing an intuitive dashboard to monitor production systems, visualize machine status, receive real-time alerts, and track continuity and recovery progress. It simplifies complex system information into easily understandable formats such as charts, indicators, and notifications, enabling faster and more informed decision-making.

The Data Acquisition Layer is responsible for continuously collecting real-time data from multiple industrial sources, including sensors, PLCs, robotic systems, enterprise applications (ERP/MES), and network devices. It ensures that incoming data is properly validated, timestamped, and standardized before being forwarded for analysis, forming the foundation for accurate monitoring and threat detection. The Threat Detection Layer processes this data using AI and machine learning models to analyze machine behavior, network traffic patterns, and control commands. By comparing live data with predefined baseline patterns, the system can identify anomalies, suspicious activities, and potential cyber threats at an early stage, reducing the risk of large-scale disruptions.

The Resilience and Recovery Layer ensures uninterrupted operations by responding immediately when threats are detected. It performs automated containment by isolating

affected systems or network segments, preventing the spread of attacks. It also activates digital twin-based backup mechanisms to maintain production continuity and uses self-healing techniques to restore compromised systems using trusted configurations and backups. Finally, the Analytics and Reporting Layer manages the storage of logs, incident records, and operational data. It generates detailed reports and visual insights related to system performance, threat detection, and recovery processes. These insights support auditing, compliance, performance evaluation, and continuous system improvement. Overall, this architecture provides a comprehensive and intelligent framework that combines real-time monitoring, proactive threat detection, automated response, and data-driven analysis to ensure secure and resilient smart manufacturing operations.

3.4 ANOMALY DETECTION MODEL

The anomaly detection module is responsible for identifying suspicious behavior within the manufacturing environment by analyzing both cyber and operational data. When live data enters the system, AI models compare it with predefined baseline behavior to detect deviations. The detection process considers factors such as sensor value deviations, abnormal machine cycles, unauthorized PLC commands, unexpected user login activities, and unusual network traffic patterns. Based on this analysis, the model generates an anomaly score ranging from 0 to 1, where values closer to 0 indicate normal behavior and values closer to 1 indicate high-risk abnormal activity. This multi-source detection approach enhances reliability by combining both cyber indicators and physical operational anomalies to accurately identify potential threats.

3.5 RESILIENCE AND CONTINUITY MODULE

The resilience module ensures that manufacturing operations continue securely even during cyber incidents. Once a threat is confirmed, the system initiates a series of automated actions, including isolating affected machines or network zones, blocking suspicious communication routes, activating digital twin backup workflows, and switching critical processes to safe fallback modes. At the same time, unaffected production lines are preserved to maintain overall operational continuity. For example, if a robotic station is compromised, only that specific zone is isolated while the rest of the factory continues functioning normally. This targeted containment strategy prevents complete system shutdown and significantly reduces operational losses.

3.6 RECOVERY AND SELF-HEALING SYSTEM

The recovery module is designed to automatically restore affected systems after the threat has been contained. The recovery process includes restoring trusted controller configurations, reimaging compromised systems, reconnecting verified devices, synchronizing physical systems with the digital twin state, and validating overall operational stability. Once recovery is completed, the system updates the dashboard with detailed logs and recovery explanations, providing transparency to administrators. This integrated self-healing approach ensures that both technical recovery processes and operational continuity are clearly communicated, enabling efficient system management and minimizing downtime in industrial environments.

CHAPTER 4

METHODOLOGY

4.1 DATA INPUT AND PREPARATION

The first stage of the system focuses on acquiring real-time industrial data from a wide range of interconnected components within the manufacturing ecosystem. These include PLC controllers, IoT sensors, robotic systems, conveyor mechanisms, ERP/MES platforms, and network infrastructure devices. Since these sources generate heterogeneous data in different formats and frequencies, the system performs a series of preprocessing steps to ensure data quality and consistency.

Each incoming data stream is validated to remove noise, missing values, or corrupted entries. It is then timestamped to maintain proper chronological order and normalized into a standardized format for uniform processing across the system. This preprocessing step is critical because accurate and clean data directly impacts the performance of downstream analytics and AI models.

Once prepared, the data is routed to multiple analytical pipelines. It supports AI-based anomaly detection, long-term trend analysis for performance monitoring, incident correlation across multiple system layers, and synchronization with the digital twin environment. Additionally, the system maintains indexed storage of historical operational data, allowing quick retrieval of baseline patterns during runtime analysis. This significantly improves detection speed, accuracy, and overall system responsiveness while enabling continuous monitoring and informed decision-making.

4.2 THREAT DETECTION MODEL

The threat detection module is designed as a multi-stage intelligent pipeline that identifies abnormal behavior in both cyber and physical components of the manufacturing system. The process begins with feature extraction, where key indicators such as machine cycle times, sensor readings, PLC command frequency, user access patterns, and network traffic characteristics are derived from the incoming data.

These extracted features are then compared with established baseline profiles representing normal system behavior under standard operating conditions. Machine learning algorithms, such as classification or anomaly detection models, analyze deviations from these baselines and assign an anomaly score to each event. This score reflects the severity and likelihood of a potential threat.

Based on predefined thresholds, events are categorized into risk levels such as low, medium, or high. High-risk anomalies trigger immediate alerts and are forwarded to the response system for further action. The module is capable of detecting a wide range of threats, including unauthorized access attempts, abnormal machine behavior, command injection attacks, and unusual network traffic patterns. This proactive and adaptive detection approach enables early threat identification, minimizing damage and preventing escalation into critical failures.

4.3 CONTINUITY ACTIVATION AND DIGITAL TWIN DEPLOYMENT

When the system detects a threat that exceeds predefined risk thresholds, the continuity The continuity module is automatically activated to ensure uninterrupted industrial operations and forms a critical part of the system's resilience strategy. Instead of stopping production completely, it enables controlled and adaptive responses that minimize disruption and maintain essential processes during cyber incidents or system failures. A key feature of this module is the integration of a digital twin, which acts as a real-time virtual replica of the physical manufacturing environment. It is continuously synchronized with live data such as machine states, process parameters, and workflows, ensuring an accurate reflection of the system. In case of disruption, operations can be shifted to this virtual environment, allowing production to continue through alternate control logic even if physical systems are affected.

In addition, the module initiates safe-mode production, reroutes workflows to unaffected machines, schedules alternative resources, and simulates required control commands to maintain process flow. These actions are performed automatically in real time, reducing dependency on manual intervention and improving response speed. Importantly, only affected components or zones are isolated instead of shutting down the entire plant, which prevents threat propagation while keeping the rest of the system operational. As a result, downtime is minimized, productivity is maintained, and operational losses are reduced. Overall, the continuity module strengthens system resilience by enabling adaptive response, sustained operation, and smooth recovery in modern smart manufacturing environments.

4.4 INCIDENT RESPONSE AND RECOVERY VALIDATION

After a threat is successfully contained, the system enters the recovery phase to restore normal operations in a secure and controlled manner. It begins with a detailed assessment of machine states, PLC logic, network conditions, and software integrity to determine the extent of the compromise. If all components pass security checks, a safe restoration process is initiated to resume normal production. If any issue persists, a full recovery is performed using clean backups, verified configurations, and secure network reconfiguration to eliminate residual risks. During this phase, only trusted devices are reconnected, and strict authentication checks are enforced to prevent reinfection. The system also maintains continuous synchronization with the digital twin to ensure consistency between physical and virtual operations. Automated workflows help reinitialize processes, recalibrate machines, and restore normal production sequencing without manual delays. Once restoration is complete, a validation process confirms system stability by testing machine performance, verifying communication channels, and monitoring for any abnormal behavior. The system continues to observe post-recovery operations for a short duration to ensure sustained stability. Finally, the system generates a comprehensive recovery report that includes threat status, recovery time, affected zones, actions taken, production continuity performance, and future recommendations. These insights help improve future response strategies and system configurations. Overall, this automated recovery and validation mechanism ensures transparency, minimizes downtime, enhances reliability, and strengthens the manufacturing environment against future cyber threats.

CHAPTER 5

RESULTS AND DISCUSSIONS

1.1 OVERVIEW

The proposed Cyber-Resilient Smart Manufacturing system was successfully designed, implemented, and evaluated to provide a secure, intelligent, and fault-tolerant industrial environment. The platform integrates Industrial IoT monitoring, Artificial Intelligence-based cyber threat detection, automated containment mechanisms, digital twin-based continuity support, and recovery automation to ensure uninterrupted production in smart factories. The primary objective of the project was to reduce the impact of cyberattacks on manufacturing operations by enabling real-time monitoring, early threat identification, rapid isolation of compromised assets, and seamless recovery of production processes.

This chapter presents the results obtained from system implementation and testing, focusing on the performance of the monitoring module, AI anomaly detection engine, containment and recovery mechanisms, and overall system usability. The evaluation considered key factors such as the accuracy of anomaly and threat detection, the speed of automated containment response, the effectiveness of production continuity mechanisms, recovery time after incidents, and dashboard usability for decision support. Various industrial attack scenarios and failure conditions were simulated to validate the reliability and robustness of the proposed system. The results clearly demonstrate that the integration of artificial intelligence, cybersecurity automation, and resilience engineering significantly enhances operational continuity and system performance in modern manufacturing environments.

5.2 FUNCTIONAL VERIFICATION

The first phase of testing was conducted to verify that all system modules operated correctly and maintained seamless communication with one another within the integrated framework. The evaluation was performed using a simulated smart factory environment that included machines, PLC controllers, IoT sensors, and network-connected production systems, closely replicating real industrial conditions. This setup allowed comprehensive validation of both functional behavior and inter-module coordination. During testing, the system demonstrated its ability to continuously collect machine and network telemetry in real time from multiple sources. The incoming data streams were efficiently processed and passed through the AI-based anomaly detection engine, which analyzed patterns in machine behavior, control commands, and network activity. The system successfully identified deviations from normal operational baselines and promptly triggered alerts for any suspicious activity. In addition, automated containment mechanisms were activated without manual intervention, and detailed logs and reports were generated for monitoring and analysis.

A specific test scenario involved simulating an abnormal command injection attack on a PLC device. In this case, the system quickly detected unauthorized control behavior and classified the event as high risk based on anomaly scoring. It immediately isolated the compromised controller to prevent further spread of the attack. Simultaneously, the resilience module activated the digital twin backup logic, allowing production processes to continue with minimal disruption. This demonstrated the system's capability to not only detect threats accurately but also maintain operational continuity during incidents.

Overall, the results of this testing phase confirmed that the integration between data acquisition, threat detection, and resilience modules was highly effective. The system responded in a timely and coordinated manner, ensuring both security and uninterrupted production, thereby validating the reliability and robustness of the proposed framework.

5.3 AI THREAT DETECTION PERFORMANCE

One of the key evaluation metrics of the system was the performance of the AI-based threat detection engine, which was assessed under a variety of realistic industrial scenarios. These included normal production operations, insider misuse attempts, malware-like command behavior, network intrusion attempts, sensor spoofing attacks, and unauthorized machine parameter modifications. This wide range of test conditions ensured that the system was evaluated against both typical operations and potential cyberattack situations. During these tests, the AI engine continuously monitored and analyzed multiple data sources such as machine telemetry, network traffic, PLC control logic, and user access patterns. By comparing real-time data with established baseline behavior, the system was able to detect even subtle deviations that could indicate potential threats. The anomaly detection models processed this data efficiently and assigned risk levels to different events based on their severity. The results showed that the system successfully identified various abnormal conditions, including sudden deviations in machine behavior, unusually high PLC command frequency, suspicious login attempts, inconsistencies in sensor readings, and unauthorized modifications to production processes. In many cases, these threats were detected at an early stage before they could escalate into major disruptions.

Overall, the AI-based anomaly detection model demonstrated high accuracy and reliability in identifying cyber threats in real time. Its ability to provide early warnings significantly reduced the risk of operational failure, enhanced system stability, and contributed to maintaining continuous and secure manufacturing operations.

5.4 RESILIENCE AND RECOVERY RESULTS

The resilience module was evaluated by intentionally disrupting critical manufacturing nodes to simulate real-world failure and attack scenarios. During this process, the system followed a structured recovery workflow that included detecting the compromise or failure, isolating the affected assets, activating the digital twin backup environment, redirecting workloads to safe operational paths, and finally restoring normal operations after remediation. The testing results demonstrated that compromised machines were isolated instantly, backup processes were activated successfully, and production downtime was significantly reduced. Moreover, critical production lines continued to operate even during active disruptions, and recovery logs were generated automatically for analysis and tracking. Overall, the system proved its ability to maintain strong business continuity and operational resilience during cyber incidents.

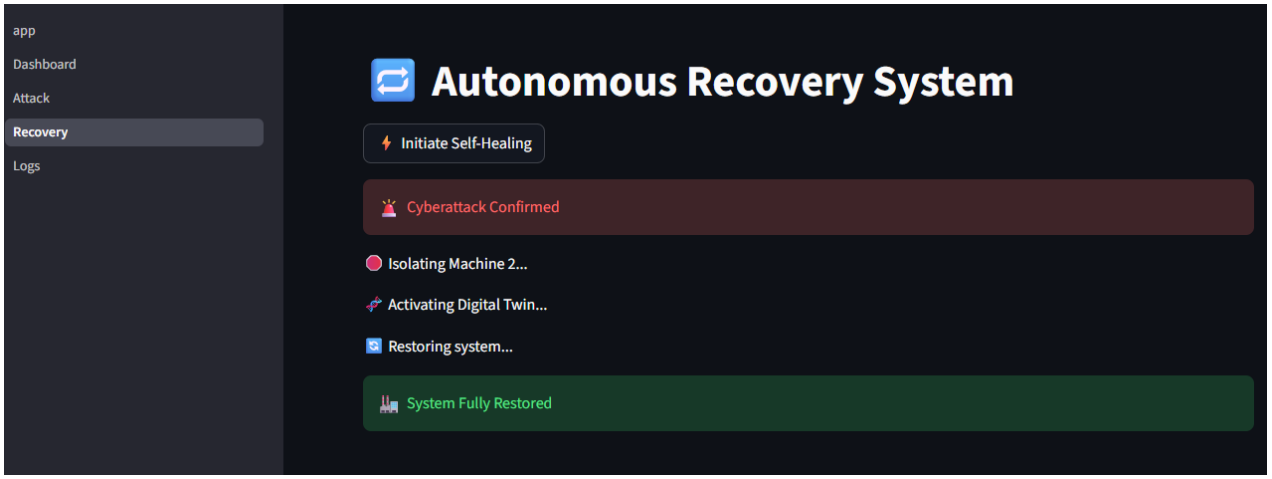

Fig. 5.4 Automated Recovery and Switchover Process

5.5 REAL-TIME MONITORING RESULTS

The dashboard continuously displayed critical information such as machine health scores, cyber risk levels, production status, active alerts, recovery state, and network security events in real time. This unified interface allowed administrators to monitor plant operations efficiently without the need to switch between multiple tools. In addition, the use of color-coded alerts significantly improved decision-making speed, where green indicated normal operation, yellow represented warning conditions, and red signified critical threats. This visual representation enhanced situational awareness and enabled faster and more effective responses to potential issues within the manufacturing environment. Furthermore, the dashboard supported real-time updates and dynamic data visualization, ensuring that users always had access to the latest system status. It also allowed quick identification of affected zones and system components during incidents. Historical data and logs could be easily accessed for analysis and reporting purposes. Overall, the dashboard improved operational transparency, coordination between teams, and overall efficiency in managing industrial cybersecurity and production processes.

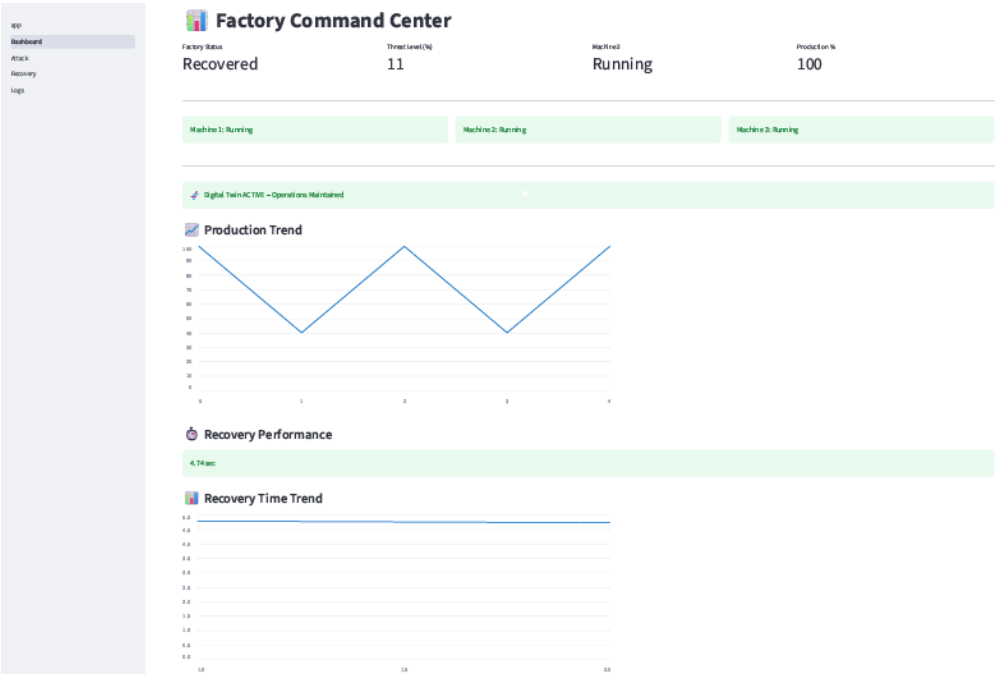

Fig. 5.5 Smart Factory Live Monitoring Dashboard

5.6 USER EXPERIENCE AND ACCESSIBILITY

The platform was evaluated by users with diverse technical backgrounds, including production supervisors, plant administrators, IT security staff, and engineers, to assess its usability and effectiveness in real industrial settings. The results indicated that the system is highly user-friendly, enabling users to easily monitor plant operations, quickly interpret alerts, trigger manual controls when required, review past incidents, and generate reports without complexity. The intuitive dashboard design and clear visualization of data reduced the learning curve, allowing even non-technical users to operate the system efficiently. Compared to traditional manufacturing monitoring solutions, users reported significantly faster response times, improved visibility across both IT and OT environments, and more confident decision-making during critical situations. Additionally, the platform enhanced situational awareness by providing real-time insights, color-coded alerts, and centralized control, ultimately increasing user confidence and ensuring more effective handling of cyber incidents and operational disruptions.

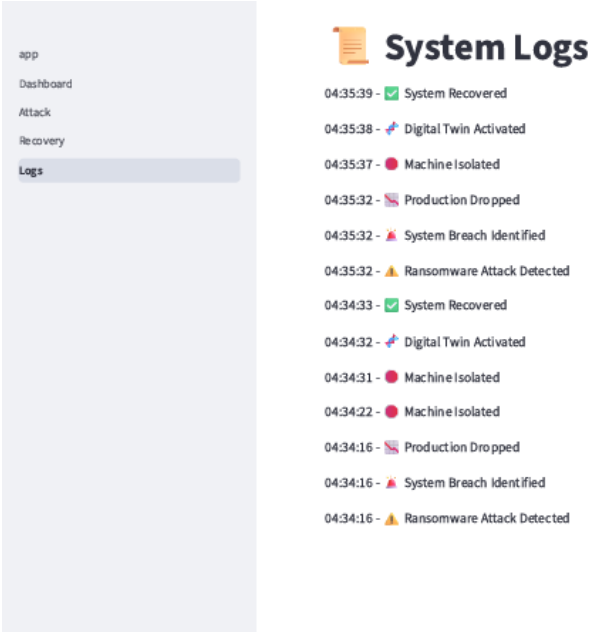

Fig. 5.6 Incident Analytics and Reporting Interface

5.7 COMPARATIVE DISCUSSION

Traditional manufacturing environments often rely on isolated monitoring tools and manual response methods, which limit their ability to handle modern cyber threats effectively. Such systems typically experience delayed threat detection, high downtime during incidents, a lack of predictive intelligence, poor coordination between IT and OT systems, and dependence on manual recovery processes. The proposed system addresses these limitations by incorporating AI-powered early threat detection, automated containment mechanisms, digital twin-based continuity support, self-healing recovery workflows, and a unified monitoring dashboard. Experimental results demonstrate that the system significantly improves cyber resilience, minimizes operational downtime, enhances production continuity, detects threats more quickly, and supports intelligent decision-making. Overall, the integration of artificial intelligence with resilience engineering provides a robust and efficient solution for modern Industry 4.0 smart manufacturing environments.

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENTS

6.1 CONCLUSION

The proposed Cyber-Resilient Smart Manufacturing platform successfully demonstrates the effective integration of Artificial Intelligence, Industrial IoT, cybersecurity automation, and resilience engineering to safeguard modern manufacturing environments. With the rapid evolution of Industry 4.0, industrial systems have become highly interconnected, increasing both efficiency and vulnerability. This project addresses these challenges by shifting from traditional prevention-based security approaches to a resilience-driven model that ensures continuous and secure operations even during cyber incidents. The system enables real-time industrial monitoring by collecting and analyzing data from multiple sources, allowing early identification of anomalies and potential threats. The AI-based anomaly detection engine proved highly effective in recognizing deviations in machine behavior, network activity, and control logic, ensuring timely detection of suspicious events. Once a threat is identified, automated containment mechanisms isolate compromised assets, preventing further spread across the system. A key strength of the platform is its resilience capability, achieved through digital twin integration and self-healing recovery mechanisms. The system ensures that critical production processes continue with minimal disruption by activating backup workflows and restoring affected components using trusted configurations. This significantly reduces downtime and maintains operational stability during cyber incidents. The evaluation results confirm that the system improves overall industrial security posture, enhances situational awareness, and supports faster and more informed decision-making. By combining intelligent monitoring, automated response, and continuity planning, the proposed framework establishes a secure, adaptive, and reliable manufacturing ecosystem. This project clearly proves that integrating smart manufacturing technologies with cyber resilience principles is essential for building future-ready industrial systems capable of operating safely in dynamic and threat-prone environments.

6.2 FUTURE ENHANCEMENTS

Although the current system demonstrates strong performance, several enhancements can further improve its scalability, intelligence, and real-world applicability. One potential improvement is the integration of predictive maintenance capabilities, where cyber monitoring is combined with machine health prediction to prevent both system failures and cyberattacks simultaneously. Another enhancement involves deploying AI models at the edge, allowing faster detection and response by processing data directly on industrial gateways. Additionally, implementing blockchain-based audit trails can ensure secure and tamper-proof logging of incidents for forensic analysis. The system can also be extended by introducing autonomous recovery agents using reinforcement learning techniques, enabling self-optimizing and adaptive recovery strategies. Expanding the platform to support multi-factory centralized monitoring would allow multiple manufacturing units to be controlled and analyzed from a single command center. Furthermore, advanced digital twin simulations can be developed to model and test cyberattack scenarios before they occur in real environments. By incorporating these enhancements, the system can evolve into a next-generation autonomous cyber defense platform capable of supporting large-scale, intelligent, and resilient smart manufacturing ecosystems.
